

# Improving Network Agility with Seamless BGP Reconfigurations

**S. Vissicchio**, L. Vanbever, C. Pelsser, L. Cittadini, P. Francois, and O. Bonaventure

*Université de Strasbourg - 19 October 2012*

# Overview

---

- ▶ BGP reconfigurations are **needed**
    - ▶ BGP is critical for ISPs
    - ▶ configuration needs to be evolved
    - ▶ running services should not be affected
  - ▶ BGP reconfigurations are **difficult**
    - ▶ current best practices do not work
    - ▶ no algorithmic approach is viable
  - ▶ We propose a reconfiguration **framework**
    - ▶ enabling anomaly-free reconfigurations
    - ▶ prototype implementation
    - ▶ evaluation and case study
-

Background

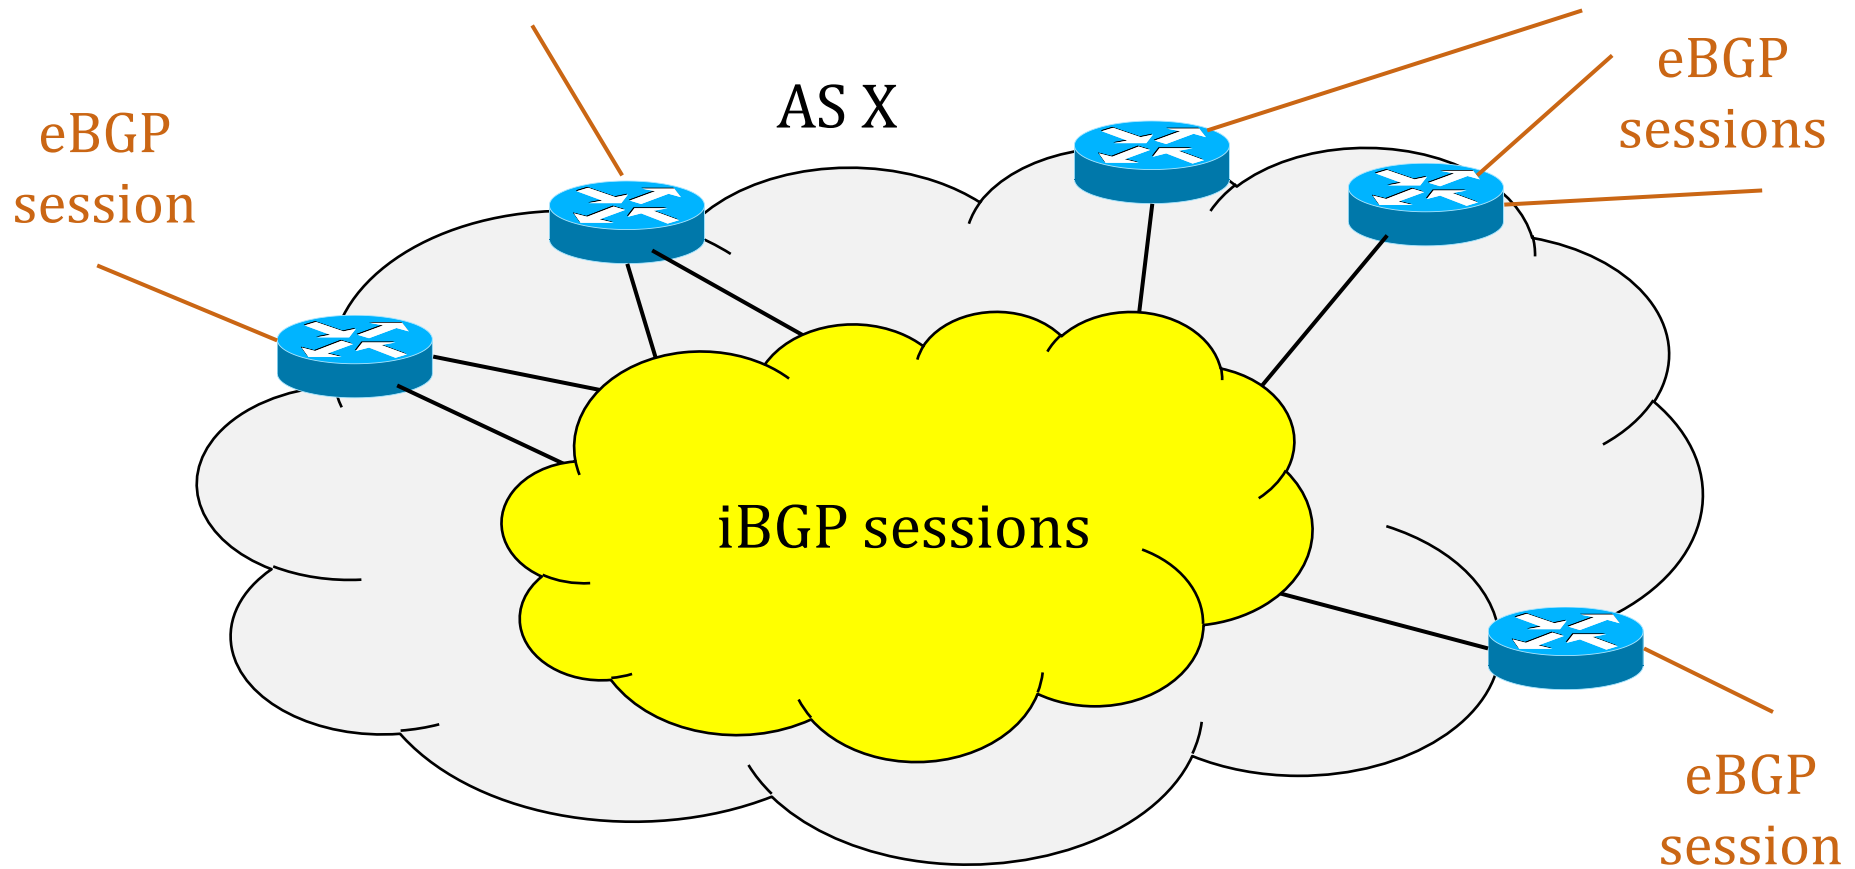

# The Internet Infrastructure

---

# We Take the Perspective of a Single AS

---

We refer to the organization of iBGP sessions as **iBGP topology**

---

# iBGP Route Reflection (RR)

---

- ▶ to scale, routers are organized in a hierarchy
  - ▶ lower layers rely on upper layer for routing information
  - ▶ we assume proper hierarchy and top layer full mesh

# Terminology

---

# Route Propagation

---

- ▶ Only best routes are propagated on **valid signaling paths**
  - ▶ Routes from non-clients are not propagated to non-clients
  - ▶ Valid signaling paths: UP\* OVER? DOWN\*

# Route Propagation

---

- ▶ Only best routes are propagated on **valid signaling paths**
  - ▶ Routes from non-clients are not propagated to non-clients
  - ▶ Valid signaling paths: UP\* OVER? DOWN\*

# Configuration Correctness

---

- ▶ Route propagation rules → **limited route visibility**
  - ▶ In turn, limited route visibility + IGP/iBGP coupling → routing and forwarding **anomalies**
    - ▶ signaling anomalies: iBGP never converges to a stable state [Griffin00]
    - ▶ dissemination anomalies: not all the routers receive a route to a given destination in the stable state [Vissicchio12]
    - ▶ forwarding anomalies: data packets incurs in deflections and forwarding loops in the stable state [Griffin00]
-

# Problem Statement

# Seamless BGP Reconfigurations

---

- ▶ Change BGP configurations ...
    - ▶ **need for evolution** and **network agility**
  - ▶ ... with no impact on services
    - ▶ intermediate configurations should be **anomaly-free**
    - ▶ **unintended traffic shifts** should not occur
  - ▶ in this talk, we focus on iBGP topology changes
    - ▶ similar considerations hold to eBGP policy modification
-

# The Need for Evolution

---

- ▶ BGP configuration has to be changed regularly
    - ▶ e.g., PoP addition / inflation or commercial relationship change
  - ▶ we performed a study on Tier-I historical data
    - ▶ data set: 20% router configs, April 2010 – July 2011
    - ▶ 90 BGP config changes / month, on average
    - ▶ BGP session additions and removals are frequent
      - ▶ session additions: 4,800 in iBGP, 1,000 in eBGP
      - ▶ session removals: 1,400 in iBGP, 230 in eBGP
    - ▶ eBGP policy changes are less frequent (but still present)
      - ▶ policy name changes: 120 in total
-

# Network Agility

---

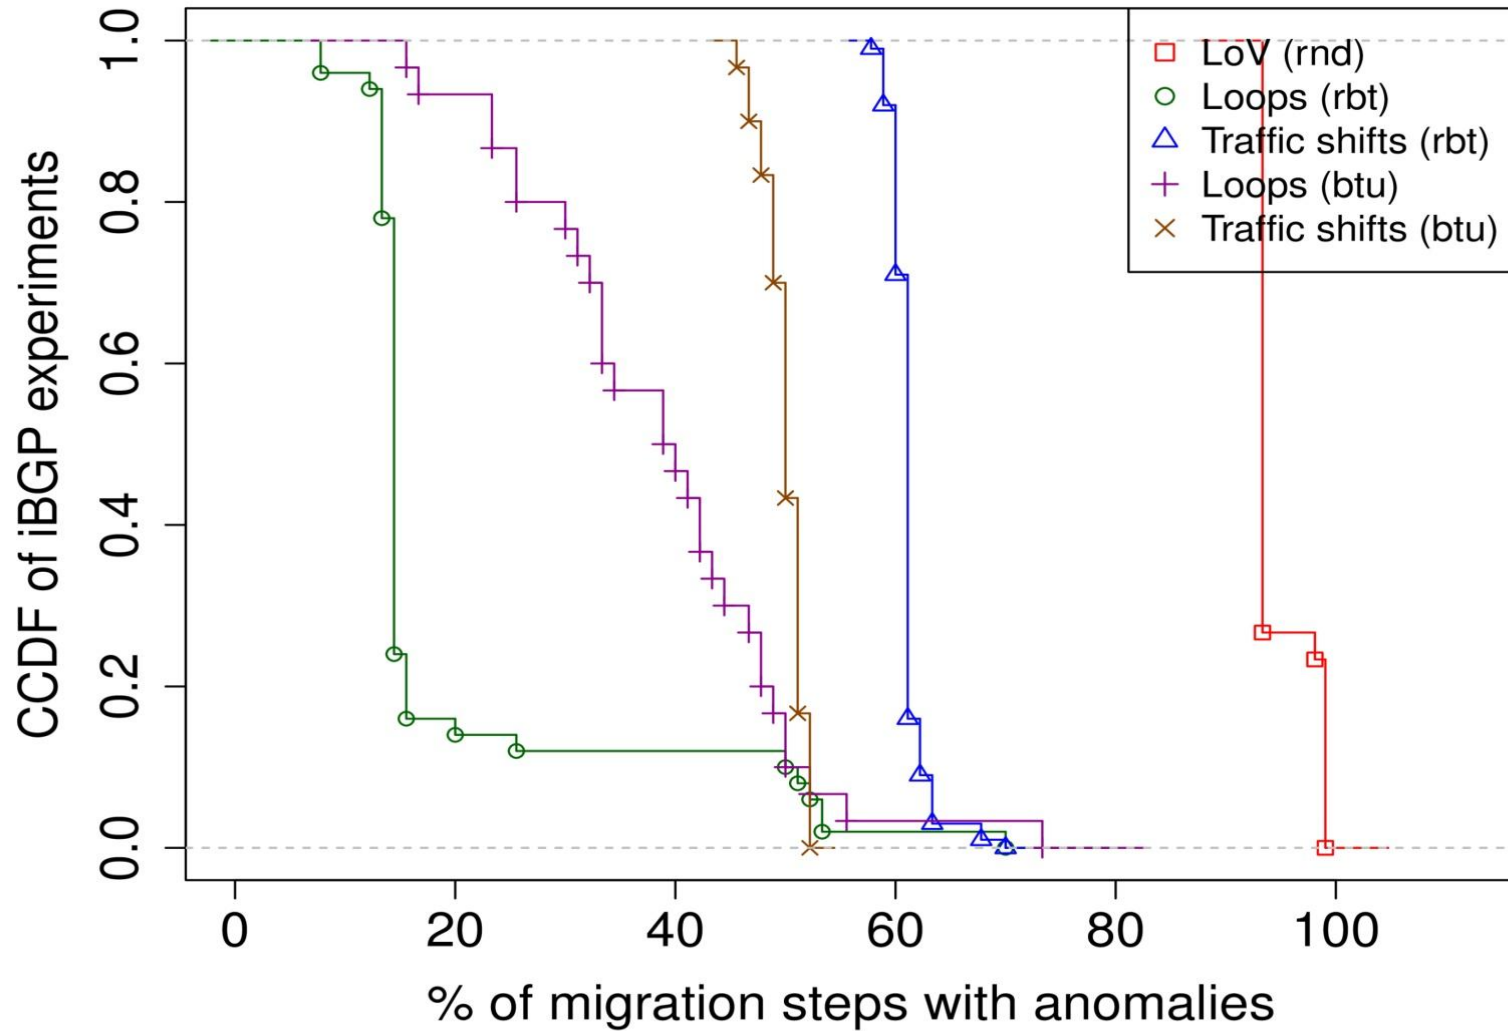

- ▶ possibilities of competitive advantage for ISPs
    - ▶ adapt routing to traffic flows
      - ▶ mirroring daily / nightly trends
      - ▶ supporting green networking
    - ▶ flexible inter-domain routing policies
      - ▶ reduce transit costs
      - ▶ flexible upstream connectivity
-

# Current Best Practices

---

- ▶ rules of thumb for simple cases
    - ▶ e.g., full-mesh to 2-layer route reflection
  - ▶ **per-router** reconfigurations
    - ▶ final configs are pushed to one route-reflector at the time
    - ▶ no operational ordering is specified
  - ▶ however, operational ordering requires extreme care
    - ▶ anomalies can occur in intermediate configs
    - ▶ both theoretically and practically
-

# Current Best Practices Do Not Work

# An Algorithmic Perspective

# The Algorithmic Problem

---

- ▶ *Input*: initial and final BGP configs
    - ▶ **anomaly-free**, by hypothesis
  - ▶ *Problem*: compute an ordering in which to add / remove BGP sessions
    - ▶ the ordering must ensure a **seamless reconfiguration**
-

# Model

- ▶ iBGP configs are modeled as **enriched graphs**
  - ▶ nodes are routers, edges are BGP peerings
  - ▶ an **ordered list of permitted paths** per node
    - ▶ only valid signaling paths are permitted
  - ▶ path preferences reflect the iBGP decision process

# Non-Solvable Example

---

initial config

final config

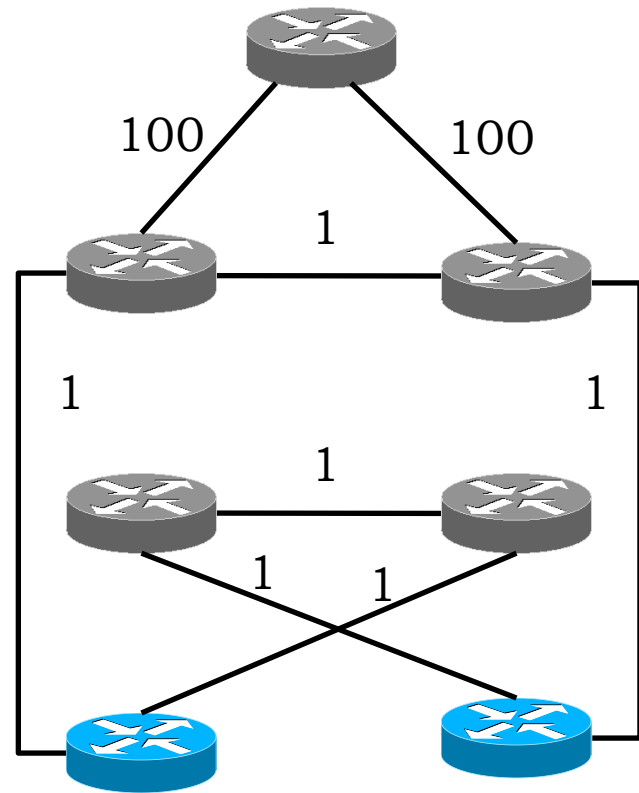

# BGP Route Preferences

BGP config

IGP config

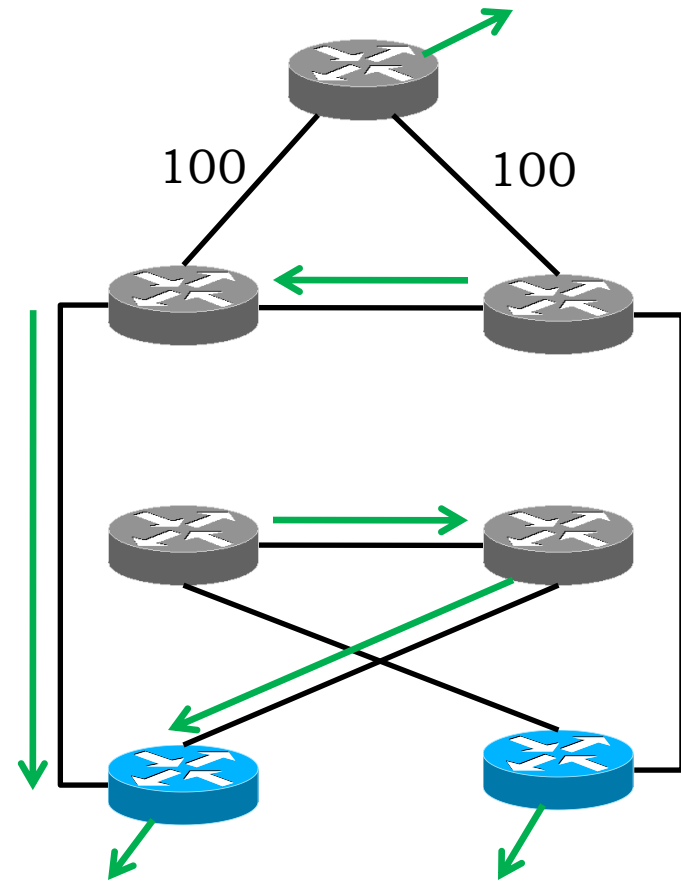

# Initial Config is Anomaly-Free

initial config

IGP config

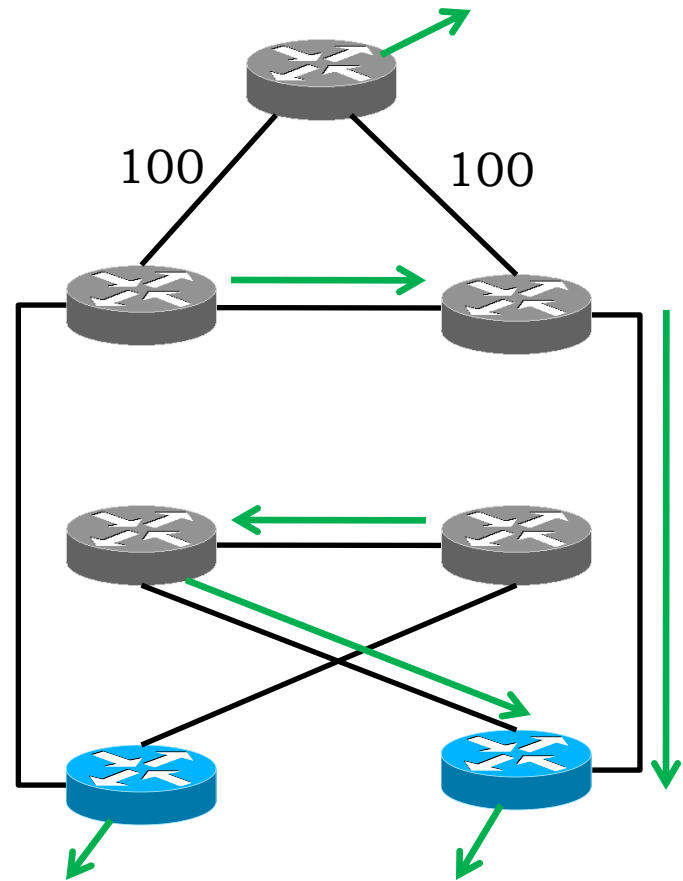

# Final Config is Anomaly-Free

final config

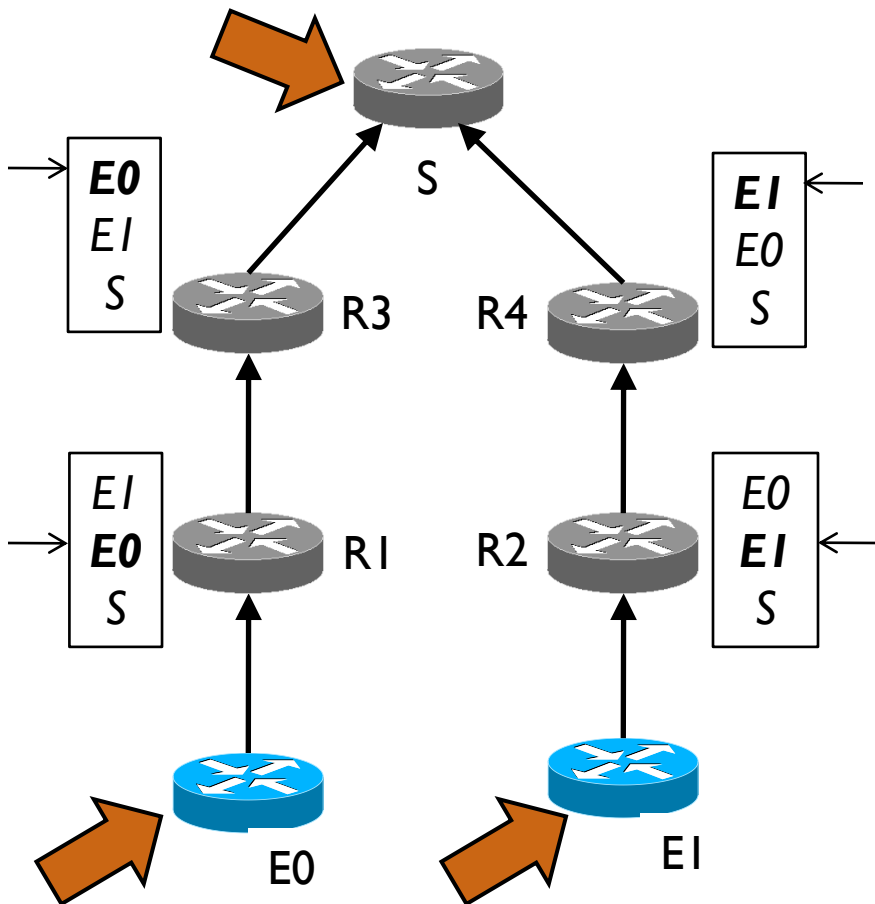

IGP config

# Case 1: Remove Before Adding

intermediate config

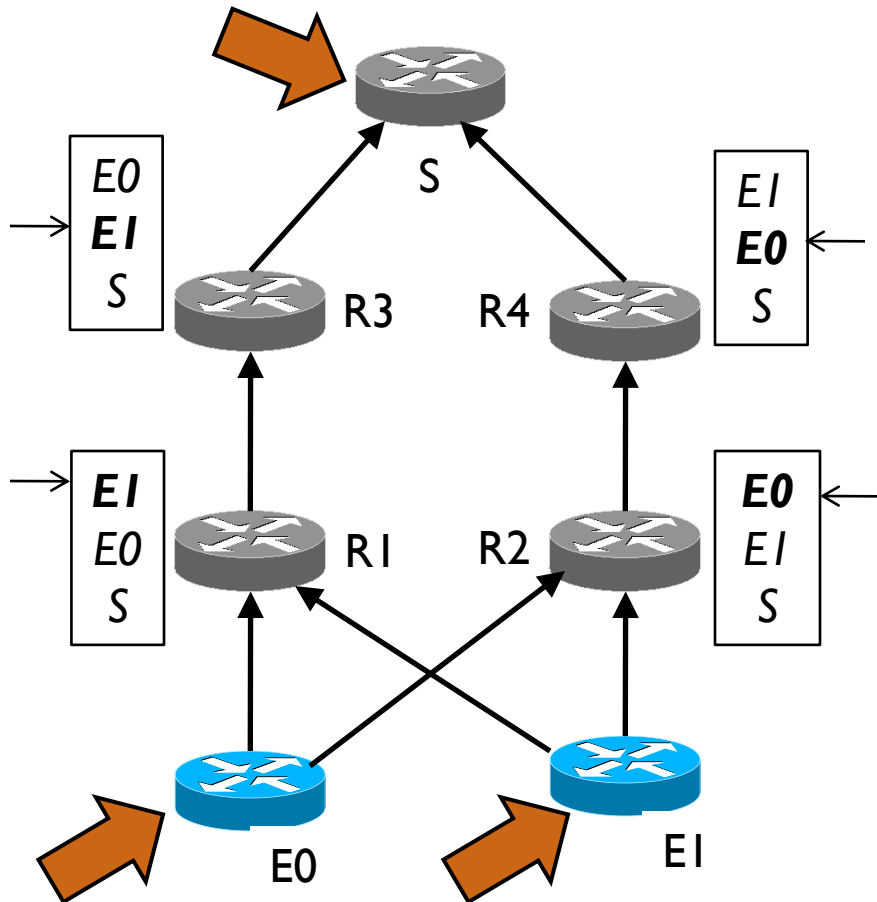

IGP config

# Case 2: Add Before Removing

intermediate config

IGP config

# More in General

---

- ▶ Examples exist in which every intermediate config is not free from
    - ▶ signaling anomalies
    - ▶ dissemination anomalies
    - ▶ forwarding anomalies
    - ▶ unintended traffic shifts
    - ▶ a combination of the above anomalies
  - ▶ Those examples exist for both iBGP and eBGP reconfigurations
-

# Complexity of the Problem

---

- ▶ Deciding if a ordering free from signaling anomalies exists is (at least) **NP-hard**
    - ▶ P-time reduction from 3-SAT
  - ▶ The same reduction applies to
    - ▶ dissemination- and forwarding-free orderings
    - ▶ cases in which only egress points are added
    - ▶ iBGP and eBGP config changes
-

# Proposed Solution

# Basic Idea

---

- ▶ *main issue*: local changes affect remote routing decisions
  - ▶ *key idea*: BGP Ships-In-The-Night (SITN)
    - ▶ two BGP processes running at the same time
    - ▶ reconfigure by switching from one process to the other
  - ▶ *related ideas*
    - ▶ IGP reconfiguration techniques [Herrero10, Vanbever11]
      - ▶ but applied to BGP
    - ▶ Shadow Configuration [Alimi08]
      - ▶ but more lightweight, and working today
-

# Requirements for SITN

---

- ▶ **multiple isolated routing processes**
    - ▶ inside each BGP router
  - ▶ **independent propagation of routes**
    - ▶ to all the processes within the same router
  - ▶ **network-wide consistent forwarding**
    - ▶ each packet must be forwarded according to only one process
-

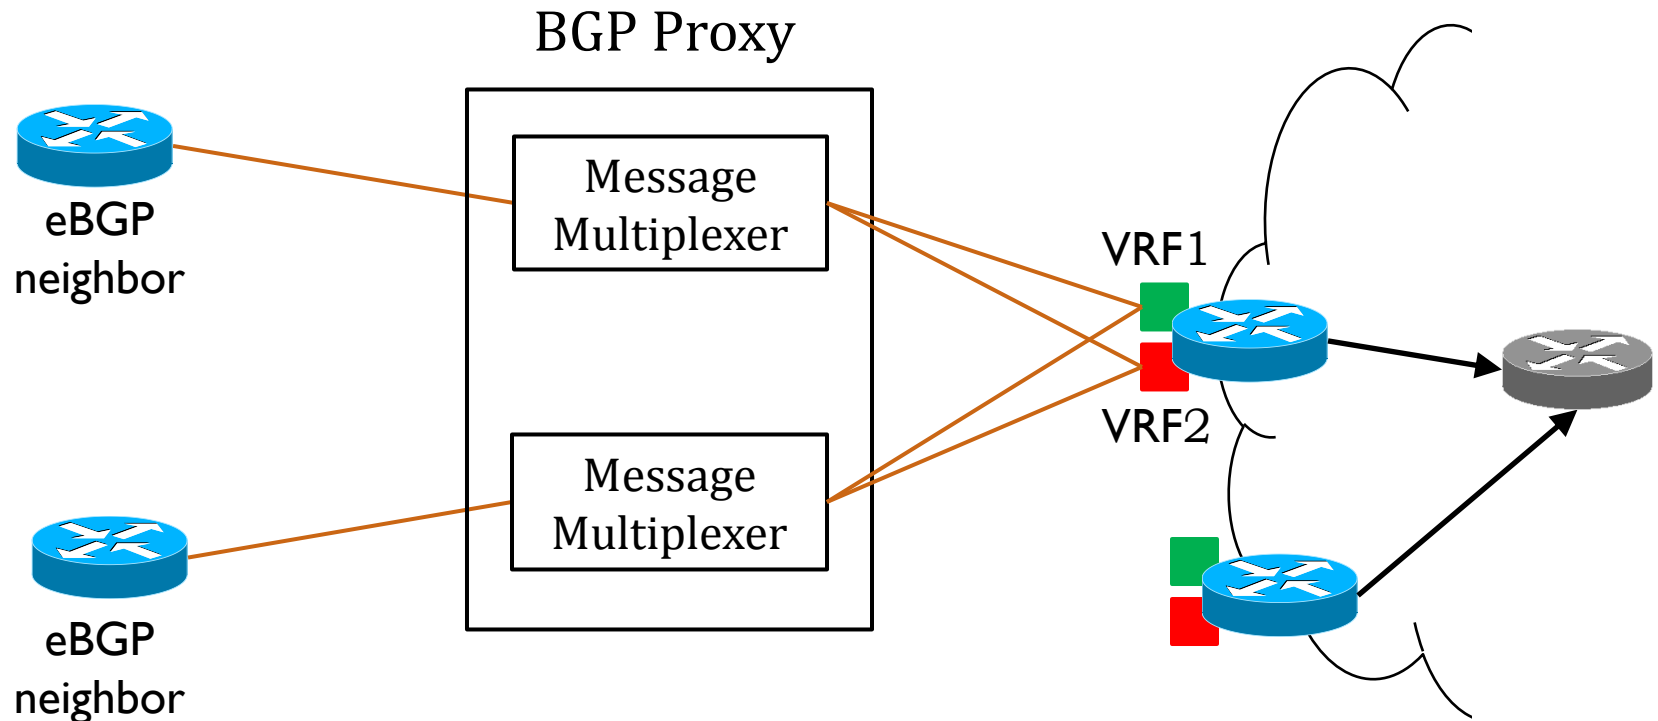

# Matching the Requirements

---

- ▶ multiple isolated routing processes
    - ▶ VRFs provide isolated routing namespaces
  - ▶ independent propagation of routes
    - ▶ **only best routes** can be imported / exported between VRFs
  - ▶ network-wide consistent forwarding
    - ▶ tagging mechanisms are available
      - ▶ packet encapsulation in GRE or MPLS
      - ▶ implicit tagging, e.g., VRF-lite
-

# The Solution in a Nutshell

---

We implemented a prototype BGP proxy in Perl (400 lines) and a provisioning system as an extension of NCGuard [Vanbever08]

---

# Case Study

---

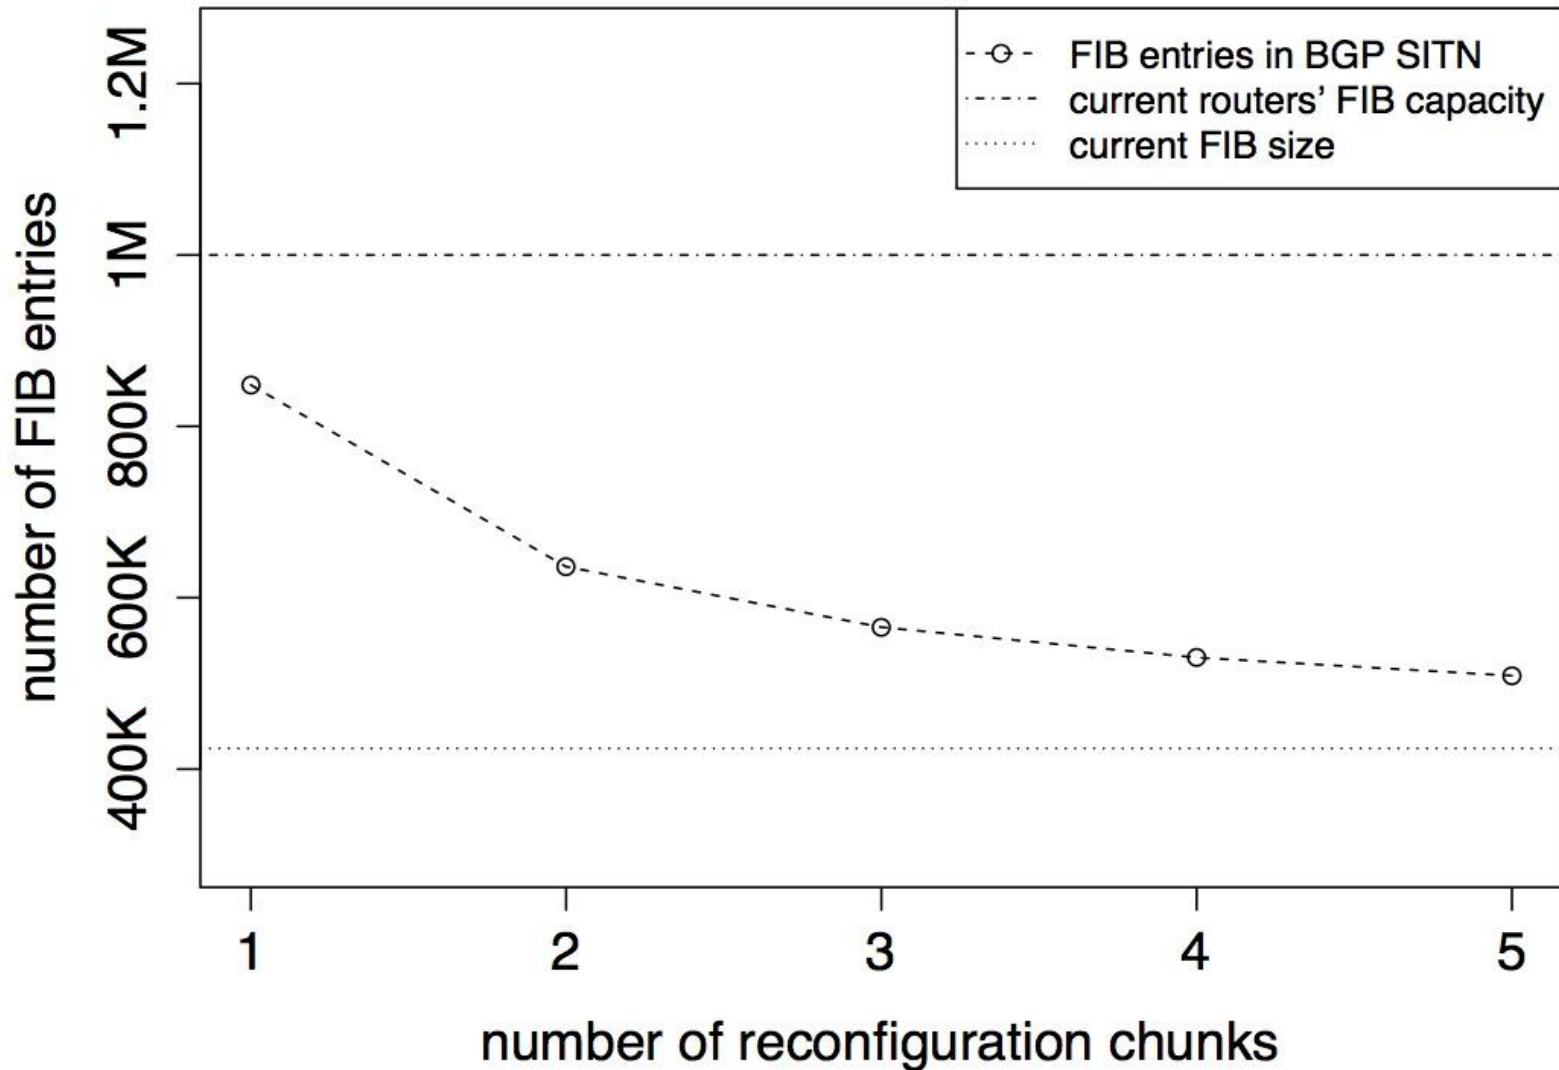

- ▶ **Reconfiguration of the Geant topology**
    - ▶ from BGP full-mesh to a three-layer RR hierarchy
    - ▶ simulation in a virtual environment
  
  - ▶ **Methodology**
    - ▶ IGP topology is consistent with L1
    - ▶ geographically-based RR topology
  
  - ▶ **Experiments**
    - ▶ comparison between current best practices and our approach
-

# Experimental Results

# Scalability (FIB)

---

# Scalability (Churn)

---

# Conclusions

---

- ▶ **First study of the BGP reconfiguration problem**
    - ▶ BGP reconfiguration is a **need** for operators
    - ▶ ensuring service continuity is **challenging**
  
  - ▶ **A suitable operational ordering does not always exist**
    - ▶ CBPs do not work in the general case
    - ▶ deciding if such an ordering exists is computationally hard
  
  - ▶ ***Proposal*: leverage two BGP control-planes**
    - ▶ VRF-based framework + working prototype
    - ▶ consistent forwarding by packet tagging
-

# Open Directions and Future Work

---

- ▶ **Algorithmic approach to simpler cases**
    - ▶ simple reconfigs (e.g., full-mesh to RR)
    - ▶ stronger assumptions on the initial and final configs
  
  - ▶ **Deployment in real networks**
    - ▶ real-world case studies
  
  - ▶ **Extension to different scenarios**
    - ▶ AS renumbering
    - ▶ combined IGP and BGP reconfigurations
-

# Thank You !!
